

WATER PHYTOSANITORY RISK MANAGEMENT IN SOILLESS CROPS

Marie Chave¹, Christine Poncet²

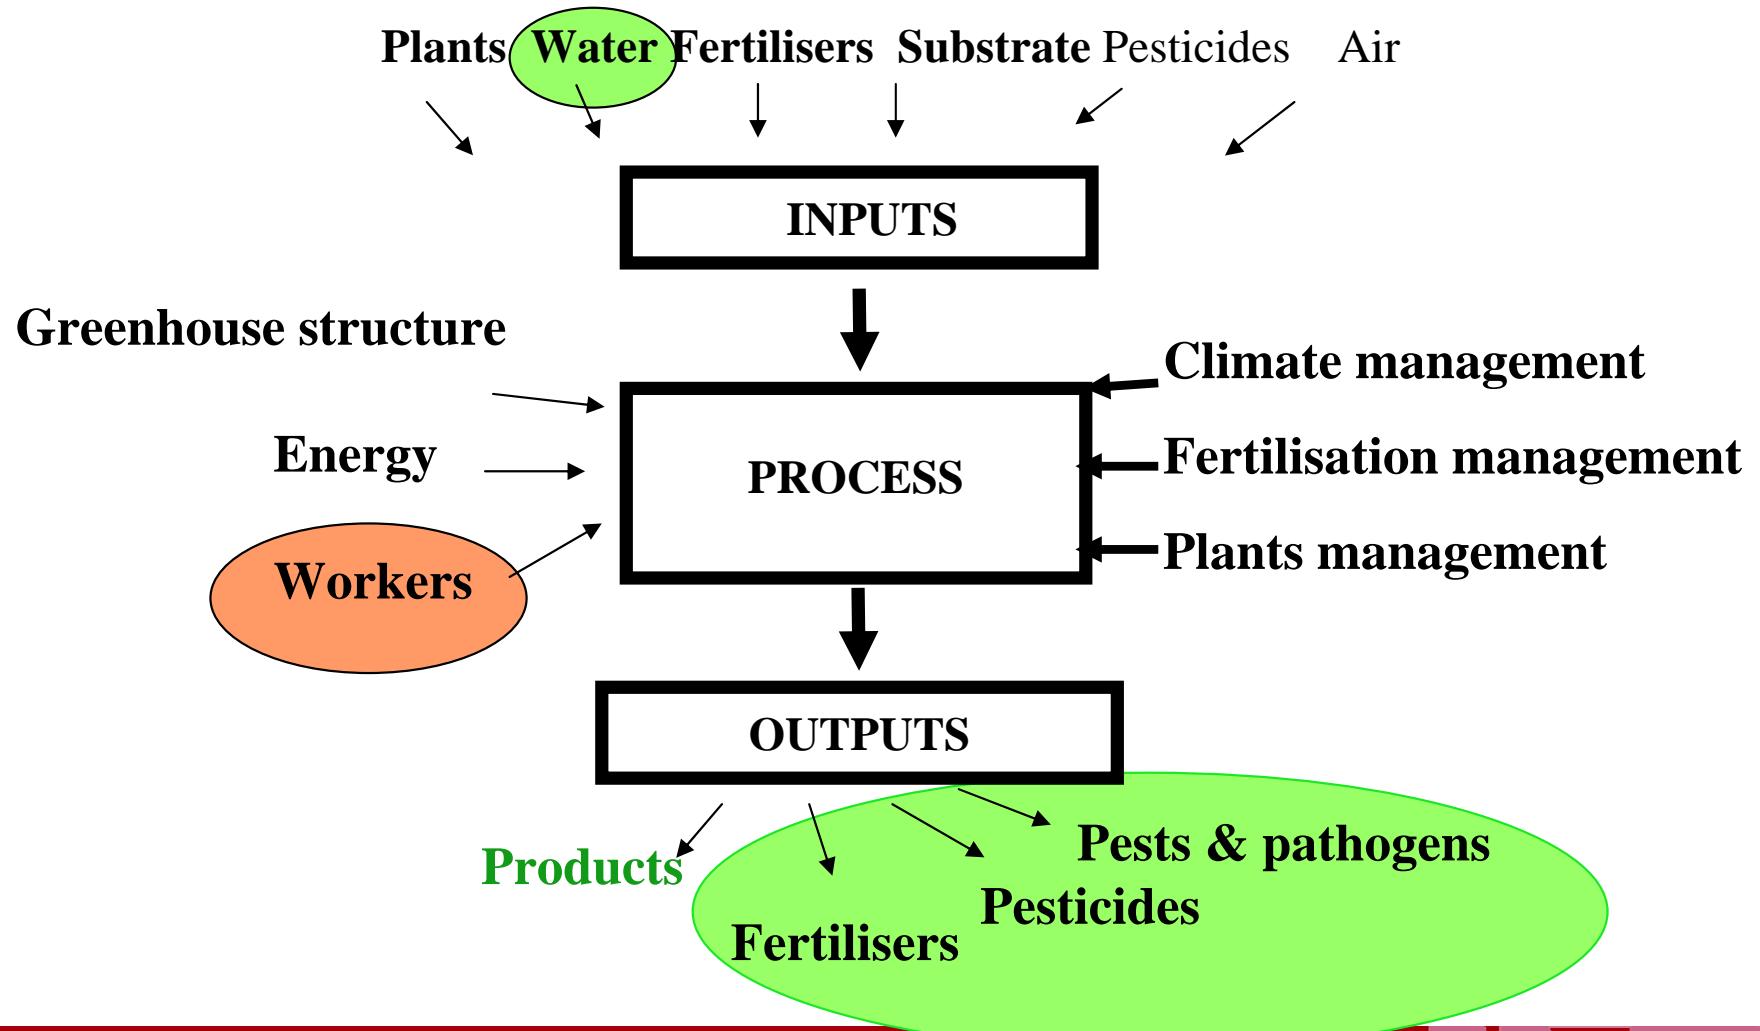

¹ INRA-ASTRO, Quartier Petit Morne, BP 214, 97232 Le Lamentin cedex 2 (**Martinique**)

² INRA- URIH, 400 route des Chappes, BP 167, 06903 Sophia Antipolis Cedex (**France**)

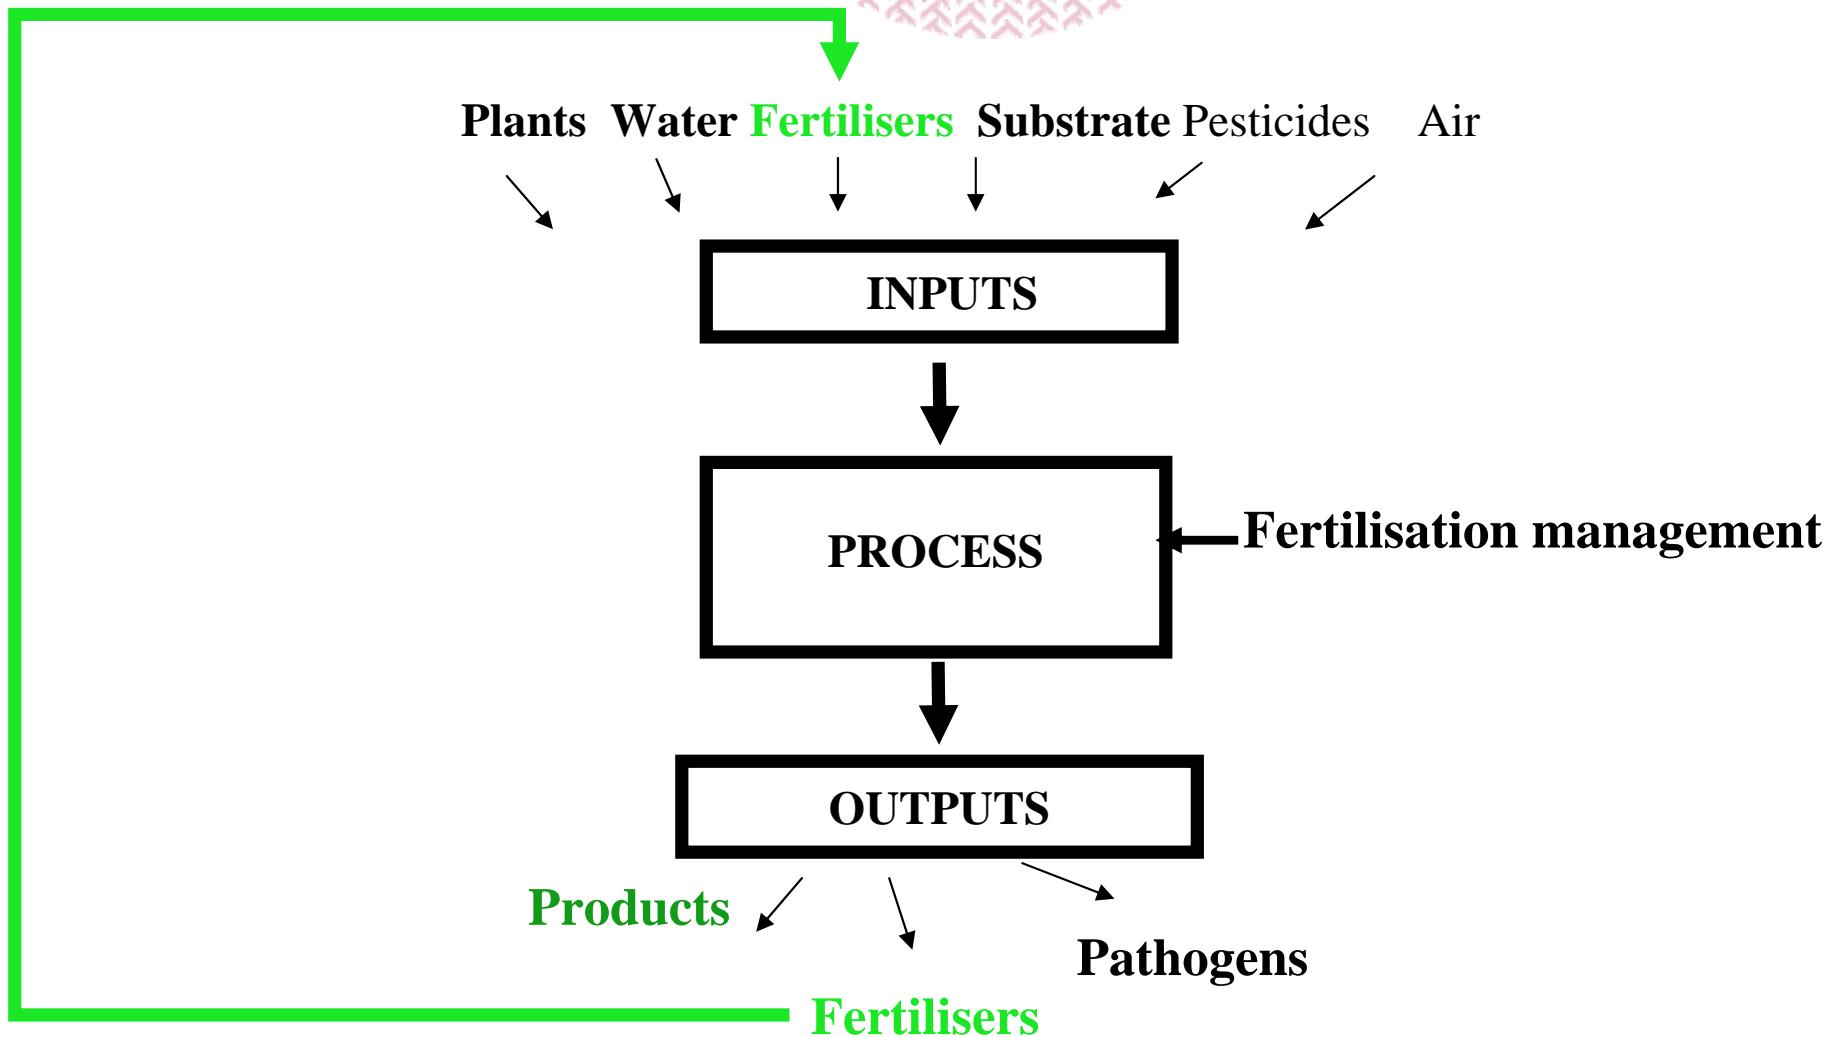

Optimisation of nutritional and environmental conditions for plant growth

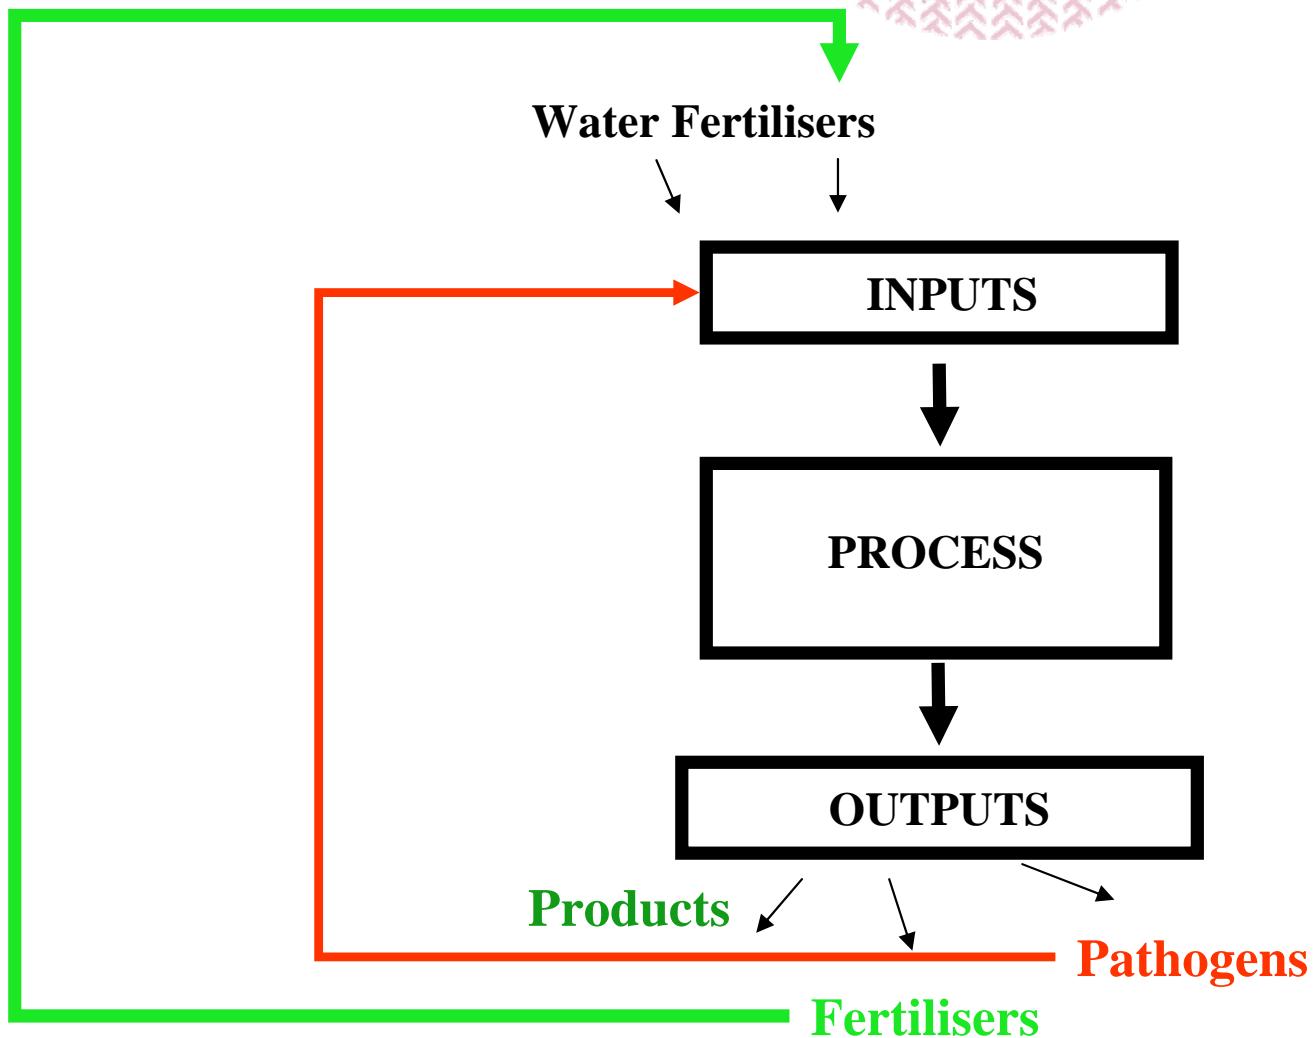

HIGH COST: economical but also social and environmental

Recycling drainage water

Recycling drainage water

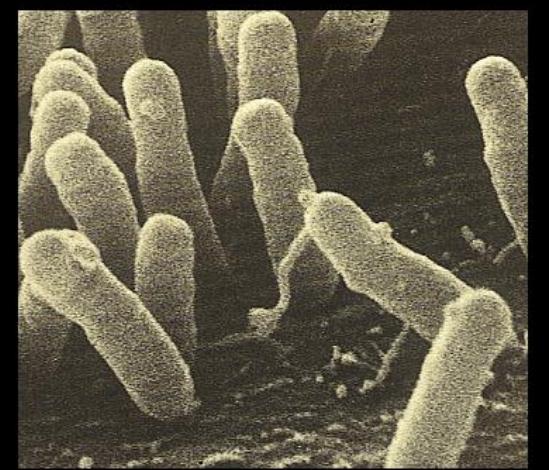

Pathogens well adapted to dissemination via water such as fungi, bacteria...

Phytophthora sp.

Fusarium sp.

*Agrobacterium
tumefaciens*

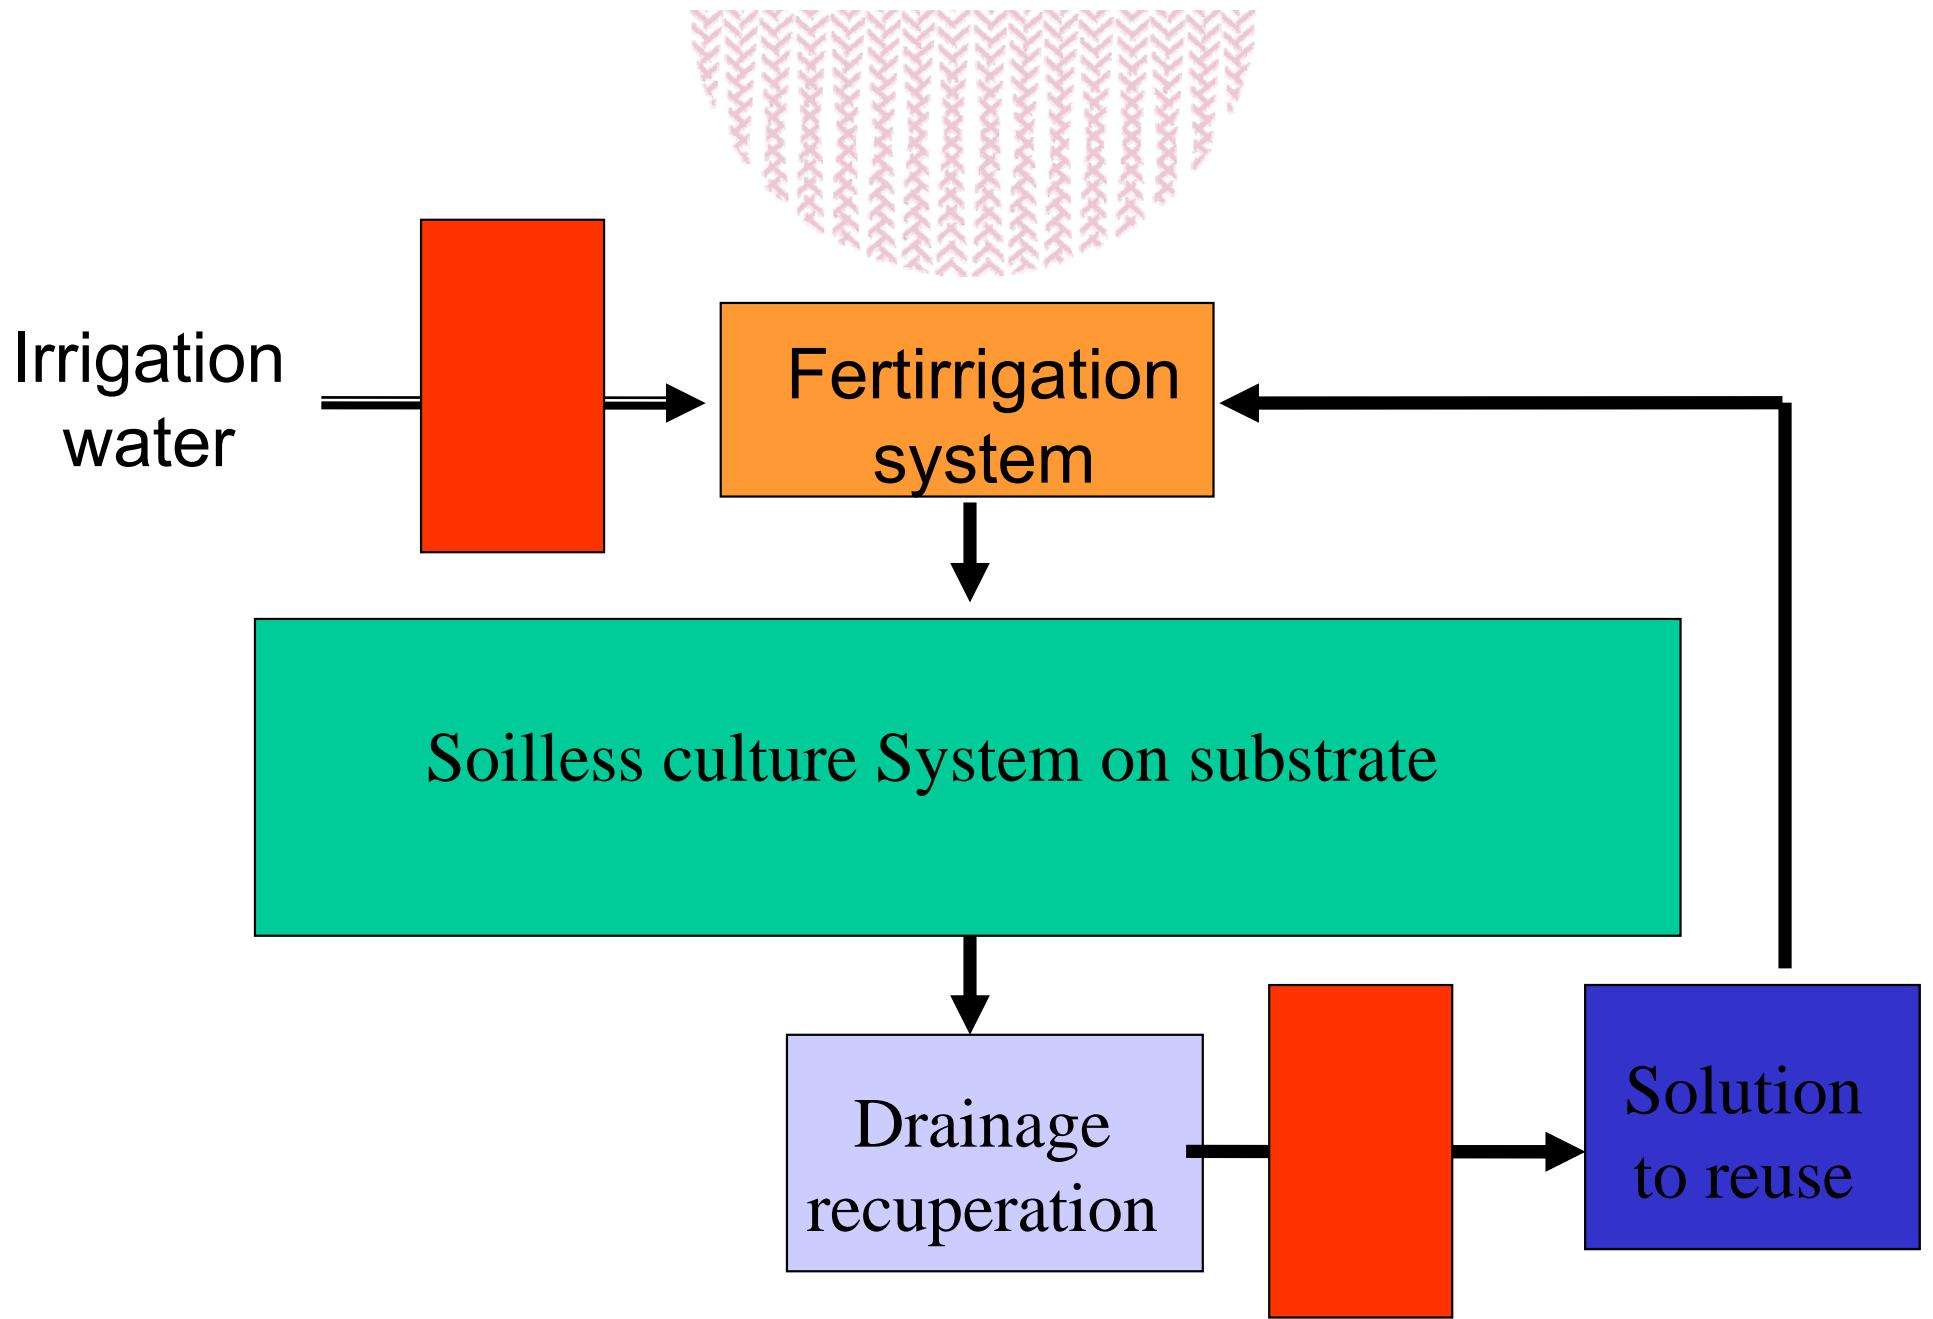

Determining pathogens density to assess phytosanitary risk for cultures is:

- too expensive
- not reliable for routine diagnostic

► Prophylactic methods for:

- Workers, plants, structure, substrate...
- water disinfection

Choice of a disinfection method

- Depends on:
 - irrigation water sanitary quality,
 - volume to be treated,
 - physico-chemical properties of the solution,
 - cost of investment and functioning
 - ...

- **Biological: partial disinfection:**
ex: slow sand filtration
- **Chemical : action on nutrients**
ex: ozone, gaseous chlorine treatments
- **Physical : efficiency depends on water quality**
ex: thermodisinfection, UV treatment

- 
- All these methods acts on water
 - What about roots where pathogens interact with plants?

Objective

- What is the influence of nutrient solution physico-chemical management on bacterial communities dynamics?

- INRA- URIH (Research Unit on Integrated Horticulture)

» Bacterial communities adhering to roots were subjected to physico-chemical regulations

➤ Assessment of rhizoplane microbial communities' dynamics by molecular method: PCR-SSCP fingerprinting

PARTIAL RESULTS

- Although EC and temperature variations, pH represent a strong stabilisation factor for roots' microbial communities

Chave & al, 2008, *Crop protection*

DISCUSSION

- Regulation of the **physicochemical environment of roots contribute to manage rhizosphere communities**
- enhancement of rhizosphere communities robustness could be a way to exclude soilborne pathogens

Conclusions- Perspectives

- Protected agriculture process (climate, fertirrigation management, ...) increase productivity and can also be tools to manage pests and pathogens.
- Protected agriculture can be developed in a sustainable way integrating: economic but also social and environmental issues

Thank you for your attention!
